

Since your app is a PWA (Progressive Web App), you have a unique opportunity to bridge the gap between a "website" and a "native app." Because you're targeting mobile users specifically, here are four powerful native-like features you can implement right now to make it feel like a professional Android/iOS radio app:

1. Lock Screen & Notification Controls (Media Session API)

Currently, if a user locks their phone, they might just see a generic browser notification. With the **Media Session API**, you can show the station name, artist, and album art on the lock screen, and allow them to Play/Pause or "Skip" to the next station in your list without unlocking the phone.

- **Feature:** Update metadata every time a new station starts.
- **Pro Tip:** Map the "Next" and "Previous" hardware buttons to cycle through your filtered list or "Favorites."

2. Native Share Integration (Web Share API)

Instead of users having to copy the URL manually, you can trigger the native mobile share sheet.

- **Feature:** Add a "Share Station" button.
- **How it works:** When tapped, it opens the Android/iOS system menu to send the station link directly to WhatsApp, Telegram, or SMS.
- **Deep Linking:** Ensure your URLs (like `wimapp.tech/?station=xyz`) automatically play that station when opened.

3. Tactile Feedback (Vibration API)

Mobile apps feel "expensive" when they provide physical feedback.

- **Feature:** Add a tiny **10ms - 20ms "thump"** when a user clicks a station or toggles the Equalizer.
- **Code Tip:** Use `navigator.vibrate(10);`. It's a small detail that makes the UI feel much more responsive and "solid" under the thumb.

4. App Shortcuts (Manifest Shortcuts)

When a user long-presses your app icon on their home screen, you can show "Quick Actions."

- **Feature:** Add shortcuts like **"Play Favorites"** or **"Search Stations."**
- **Benefit:** It saves the user 2-3 taps and makes the PWA feel deeply integrated into the OS.

A Technical Comparison for your PWA Strategy

Feature	Standard Web	PWA + Native APIs	User Impact
Lock Screen	Empty or generic	Artist, Logo, Play/Pause	High (Control while walking/driving)
Sharing	Copy/Paste URL	Native System Share	Medium (Social growth)
Interactivity	Visual only	Haptic (Vibration) feedback	High (Premium feel)
Connectivity	Fails when offline	"Offline Mode" / Cached UI	High (Reliability)

When you're ready to dive into the code, which one of these would you like to tackle first? I can provide the specific JavaScript snippets for any of them!
