

I've analyzed your app at wimapp.tech. It's a very functional and lightweight tool, and I love that you've included advanced features like a **9-band Equalizer** and **Flat Loudness**—those are rare in web-based radio players and a great "power user" selling point.

Currently, the design is very "desktop-first" (a large grid with a sidebar/header layout). On mobile, this often leads to small touch targets and a lot of vertical scrolling.

Here are specific design ideas to modernize the layout for mobile:

1. The "Now Playing" Sticky Bar (Essential)

Right now, the player controls are at the top. On mobile, if a user scrolls down the list to find a new station, they lose sight of the "Stop/Pause" button.

- **The Idea:** Keep the player controls in a **fixed bottom bar**.
- **Mobile Benefit:** This keeps the most important actions within "thumb reach."
- **Visuals:** Show a small thumbnail of the station logo, the name, and a Play/Pause button. Tapping this bar could slide up a "Full Player" view (like Spotify) where your Equalizer and Loudness settings live.

2. Modernize the List (Card-based UI)

The current list is very text-heavy and look like a database table.

- **The Idea:** Switch from a "row" to a "card" or a "rich list item."
- **Design:**
 - **Left side:** A large, rounded station icon (favicon).
 - **Center:** Station name (Bold) and tags (Genre/Country) as small, colorful "pills."
 - **Right side:** A small "heart" icon for favorites and the Bitrate badge.
- **Why:** On mobile, users scan icons faster than text. Increasing the row height makes it easier to tap the right station.

3. Move Filters to a "Bottom Sheet"

Currently, the filter options (Bitrate, Country, Genre) and the Search bar take up the top 40% of the screen. This pushes the actual content (the radio stations) off-screen.

- **The Idea:** Use a single "Filter & Search" button at the top. When tapped, it opens a **Bottom Sheet** (a drawer that slides up from the bottom of the screen).
- **Why:** This follows "Mobile First" patterns. It keeps the main screen clean for browsing stations but makes deep filtering only one tap away.

4. Group the Equalizer (Accordion or Tab)

Your Equalizer is great, but it takes up a lot of vertical space.

- **The Idea:** Place the Equalizer and "Flat Loudness" toggle inside an **"Audio Settings" tab** or an expandable accordion.

- **Visuals:** Use a "gear" or "sliders" icon. On mobile, you could even use a "Glassmorphism" effect (semi-transparent background) for the Equalizer panel to make it look premium.

5. Interaction & Feedback

- **Skeleton Screens:** Instead of a "loading" text, show grey pulsing shapes that look like the station cards while the API is fetching.
- **Active State:** When a station is playing, give that specific card a subtle glowing border or a small "equalizer animation" icon next to the name. This helps the user remember which station they clicked after scrolling.

Technical "Quick Wins":

- **Safe Area:** Ensure your bottom controls account for the iPhone "home bar" or Android navigation gestures (add `padding-bottom: env(safe-area-inset-bottom);`).
- **Touch Targets:** Ensure every button is at least **44x44 pixels**. Currently, some of the filter text links look a bit small for larger thumbs.

If you'd like, I can provide a snippet of CSS/Tailwind or a React layout structure to help implement the "Bottom Player Bar" specifically!
